Chapter 3

Databases and Data Warehouses: Building Business Intelligence

How Can a Business Increase its Intelligence?

FreakingNews.com

Summary

 Overview of Main Concepts
 Details/Design of a Relational Database
 Creating Business Intelligence using Databases
 Special Issues in Data Management: Ownership and Security

Information processing in a business

 Businesses use IT tools to manage and organize the information they keep.

- Online transaction processing (OLTP) gathering, processing information and updating information as soon as it is entered
- Online analytical processing (OLAP) manipulation of information to support decision making

Information processing in a business

- On-line Transaction Processing (OLTP) is supported by operational databases & database management systems (DBMS). It
 - collects input information e.g. from sales and orders

- updates existing information

 On-line Analytical Processing (OLAP) is supported by data warehouses and datamining tools. It creates business intelligence for decision making.

Business Intelligence (BI)

Business intelligence is an organization's collection of information about customers, competitors, business partners, the business environment and internal operations. *BI* is necessary for making appropriate business decisions. To create *business intelligence*, knowledge workers need:

- data
- information
- appropriate IT tools

Creating Business Intelligence

The Relational Database Model
 Database – collection of information that is organized and accessed according to the logical structure of that information.

Relational database – series of logically related 2-D tables or files for storing information in a database. The term relation refers to the 2-D table or file. A relational database is made up both the information and the logical structure of that information.

Fig 3.2: Solomon's database is made up of five relations

| ORDER FILE | | | | | | | | | |
|-----------------|---------------|--------------------|---------------------|------------------|--------|-----------------|--------------|--|--|
| Order Number | Order Date | Customer Number | Delivery Address | Concrete Type | Amount | Truck Number | Driver ID | | |

| 4 | Premier marble (concrete with crushed marble aggregate) | 111 | Ford | 6/17/1999 | | | |
| 5 | Premier shell (concrete with shell aggregate) | 222 | Ford | 12/24/2001 | | | |
| | | 333 | Chevy | 1/1/2002 | | | |

LO1 3-9

In a relational database, information is organized and accessed according to its logical structure.

The data dictionary contains the logical structure for the database information. For example, the data dictionary would specify that a 10-digit *Customer Phone* field is in the *Customer* file.

Before creating relationships between files, you must choose a primary key for each file

Primary key – field (or group of fields) that uniquely describes each record in the file e.g. the customer number uniquely identifies a customer in the customer file

 Foreign key – primary key of one file that appears in another file

Database files are connected using common fields e.g. The Order file and Truck file are connected using Truck Number

Defining the logical structure of a relational database

- Integrity constraints are rules that help ensure the quality of information e.g. when an order is input into the Order file, the customer must already exist in the Customer file.
- The *data dictionary* defines each type of information in a table e.g. format, length.
- Foreign keys must be found as primary keys in another file e.g. a Customer Number in the Order table must also be present in the Customer table.

Database Management System (DBMS)

A **DBMS** is used to specify the logical requirements for a database as well as provide the means by which information is accessed.

A database management system has five software components.

- 1. DBMS engine
- 2. Data definition subsystem
- 3. Data manipulation subsystem
- 4. Application generation subsystem
- 5. Data administration subsystem

First component of a DBMS: the DBMS Engine

The *DBMS engine* accepts *logical* requests from other DBMS subsystems, converts them into the *physical* equivalents, and accesses the database and data dictionary on a storage device.

Physical view – how information is physically arranged, stored, and accessed on a storage device e.g. customer table is stored on a particular track and sector on the computer's hard drive

Logical view – how the knowledge worker arranges and accesses information

e.g. may sort the customer file by customer ID

Second component of a DBMS: the data definition subsystem

The data definition subsystem helps the user create and maintain the data dictionary. It defines the structure of the files in the database

When creating the data dictionary, the logical structure of the database is defined. The following are examples of logical properties that can be specified for a field in the data dictionary:

- Field name e.g. SIN
- Data type e.g. alphabetic
- Default value e.g. 000-000-000

Third component of a DBMS: the data manipulation subsystem

- The data manipulation subsystem helps you add, change, and delete information in a database and query it to find valuable information. It is the main means by which a user works with the information in a database.
- The data manipulation subsystem includes views, report generators, query-by-example tools, and structured query language

View

The data manipulation subsystem's *view* allows you to see the contents of a database file, make changes, and query the database to find information.

Query-by-Example Tool

The data manipulation subsystem's *QBE tool* helps you identify the files in which to look, fields to query or display and the selection criteria to be used.

e.g. for customer number 4567, display the customer number, employee last name and employee first name

| Query1 | | | | | | | | | × | Figure 3.7 |
|----------------------------|--|--------------------|---------------------|---------------|-------------------------------|----------|----------------------|---|----------|--|

LO2 3-21

Sol performs a query by creating a

 SQL performs a query by creating a statement with the 3 parts
 SELECT...FROM...WHERE.

 IT professionals often use SQL to specify the criteria for searching through a database.

Fourth component of a DBMS: the application generation subsystem

The *application generation subsystem* is used by IT professionals to enhance transaction processing. It includes tools for creating data entry screen layouts as well as programming languages and interfaces for the DBMS.

Fifth component of a DBMS: the Data Administration Subsystem

The *data administration subsystem* is used by database administrators to manage the overall database environment. This subsystem provides facilities for:

- -Backup and recovery
- -Security management
- -Query optimization
- Concurrency control
- -Change management

Components of the data administration subsystem

- Backup and recovery creation of a second copy of the information so that it can be recovered should there be a problem with the database
- Security management control of who has access to what information
- Query optimization means by queries are enhanced and response time is minimized

 Components of the data administration subsystem
 Reorganization - physically rearranging the storage of the information so it matches how it is usually accessed

Concurrency control - addressing how the database is updated should many users want to change the same information at the same time

 Change management - assessing the impact of proposed changes to the database's structure

Data Warehouse

- A data warehouse is a large collection of information gathered from many operational databases. It creates business intelligence for business analysis and decision making.
- A data warehouse contains summarized information. It does not contain every detail of every transaction e.g. every sale.
- Data warehouses support on-line analytical processing (OLAP) but not on-line transaction processing (OLTP).

A data warehouse is multidimensional.

A data warehouse has more than 2 dimensions. In this hypercube you could retrieve product information by product line and region (columns & rows), by year (1st layer), by customer segment (2nd layer) and by timing of advertising (3rd layer).

Data-Mining Tools

Data-mining tools are used to query information in a data warehouse.

Data-Mining Tools

- Query-and-reporting tools (e.g. QBE tools, SQL, and report generators) - making simple queries and reports
- Intelligent agents (e.g. neural networks, fuzzy logic) - using artificial intelligence when analyzing processes and looking for trends
- Multidimensional analysis tools viewing multidimensional information from a different perspective (like turning the cube to slice it differently)
- Statistical tools (e.g. time-series analysis, regression analysis) - applying mathematical models to data warehouse information

Data Marts

A data mart is a portion of the data warehouse pertaining to a specific focus. For example, marketing information could be put into a data mart for the marketing department.

LO4 3-31

Back to Business Intelligence

 Business intelligence (BI) is the collection of information from internal operations as well as information about customers, competitors, business partners, and the competitive environment.

- BI focused solely on the external competitive environment is called *competitive intelligence*.
- Knowledge workers may use BI to understand the organization's capabilities, market trends, implications of certain actions by competitors, etc.

Business

 Intelligence
 includes both
 internal and
 external
 information

Viewing Business Intelligence

A *digital dashboard* shows a snapshot of information gathered from many sources. It presents results in a format tailored to the needs of the user.

Special Issues in Data Management

- Data administration plans for, oversees the development of, and monitors the information resource in an organization. It must coordinate with the organization's strategic direction.
- Database administration addresses the more technical and operational aspects of managing and organization's information kept in databases, data warehouses, and data marts.

Access to information must be controlled.

Every effort must be made to ensure that an organization's information is accurate.

Can companies keep your personal information private and secure?

- Databases are large repositories of detailed information.
- Information is a valuable commodity. A large portion of that information is personal.
- Organizations must protect their information from theft and loss.
- There are people who want to steal your personal information from the companies you do business with.
